## **ABSTRACT**

For RL algorithms, appropriate entropy control is crucial to their effectiveness. To control the policy entropy, a commonly used method is entropy regularization, which is adopted in various popular RL algorithms including PPO, SAC and A3C. Although entropy regularization proves effective in robotic and games RL conventionally, studies found that it gives weak to no gains in LLM-RL training. In this work, we study the issues of entropy bonus in LLM-RL setting. Specifically, we first argue that the conventional entropy regularization suffers from the LLM's extremely large response space and the sparsity of the optimal outputs. As a remedy, we propose AEnt, an entropy control method that utilizes a new clamped entropy bonus with an automatically adjusted coefficient. The clamped entropy is evaluated with the re-normalized policy defined on certain smaller token space, which encourages exploration within a more compact response set. In addition, the algorithm automatically adjusts entropy coefficient according to the clamped entropy value, effectively controlling the entropy-induced bias while leveraging the entropy's benefits. AEnt is tested in math-reasoning tasks under different base models and datasets, and it is observed that AEnt outperforms the baselines consistently across multiple benchmarks.

## 1 Introduction

RL seeks to optimize the reward received by a sequential decision making system. In recent years, RL has proven to be an effective tool for training LLMs (Yang et al., 2025; DeepSeek-AI, 2025; Comanici et al., 2025). The advances of LLMs in math, coding and planning tasks has been astonishing, with their performance on competitive benchmarks drastically increasing after RL training.

The methods used in LLM-RL are predominantly policy-gradient based, e.g., the PPO (Schulman et al., 2017) family. Policy gradient based methods reinforce the sampled actions that lead to higher rewards compared to other sampled actions. However, when the optimal actions are not sampled, the policy gradient methods can over-reinforce the sampled locally optimal actions, ultimately resulting in the policy stuck at suboptimal points (Agarwal et al., 2021). The sub-optimal actions can be meaningless in deep RL and oftentimes have a large performance gap from the optimal ones (Henderson et al., 2018), e.g., in LLM tasks, the policy can be stuck at producing the correct format but incorrect results. A straightforward remedy for the issue was the so-called *entropy-regularized RL* methods (Williams & Peng, 1991), where the policy maximizes a sum of rewards and some *entropy bonus* (policy randomness). This technique was commonly used in policy-gradient methods including A3C (Mnih et al., 2016), PPO (Schulman et al., 2017) and SAC (Haarnoja et al., 2018), providing strong benefits in tasks requiring hierarchical behaviors. Intuitively, the entropy bonus keeps the policy random and explorative, thus prevents the policy from over-reinforcing certain actions and getting stuck. Moreover, entropy regularization is shown to provide strong optimization benefits both empirically (Ahmed et al., 2019) and theoretically (Mei et al., 2020; Klein et al., 2023).

However, it is observed that entropy regularization offers little gains in LLM-RL training. Specifically, the experimental results to be shown in Section 5 suggest that entropy-regularized GRPO yields minimal gain compared to basic GRPO. In addition, Cui et al. (2025) observes that the validation accuracy is unchanged under different scaling of the entropy bonus in LLM-math tasks. These results are particularly underwhelming compared to those in other deep RL tasks including robotics and games, where the benefit of entropy bonus is significant (see, e.g., (Haarnoja et al., 2018, Figure 3)). Moreover, such empirical contradiction also indicates a theoretical gap between the existing analysis

which justifies the entropy's benefit (Mei et al., 2020) and its effect in LLM-RL. Therefore, a careful study and a remedy for this issue is in dire needs, as the potential gain from entropy bonus is yet to be unlocked for LLM training.

In this work, we first give a theoretical view of the entropy effect in LLM-RL training, which explains the conventional entropy bonus's emergent issues in LLM tasks. To that end, we then propose AEnt, an entropy regularization method that uses an adaptive and clamped entropy bonus. Our main contribution is twofold:

- A theory on the entropy effect and its issues in LLM-RL. Under no entropy bonus, we show that entropy collapse indicates learning stagnancy and give a performance bound. Then we show that entropy regularization can fail to improve this result due to its self-induced bias which increases with the sparsity of optimal responses in LLM tasks.
- AEnt, a recipe to enable effective entropy regularization. Inspired by the theoretical analysis, we then propose a recipe for this issue. Instead of using the traditional entropy bonus, AEnt uses a clamped entropy defined with the re-normalized LLM policy on a size-reduced token space. The clamped entropy only smooths out policy on the reasonable responses set, which enjoys decreased bias compared to the original entropy. Furthermore, the clamped entropy bonus is scaled with a coefficient that gets automatically adjusted to balance its bias and benefits. Empirical evidence suggests that AEnt consistently improves over the baselines across multiple benchmarks.

#### 1.1 RELATED WORKS

Policy-gradient based LLM-RL algorithms. The RL algorithms used in LLM post-training have been predominantly policy-gradient based (Sutton et al., 1999). They are either based on PPO (Schulman et al., 2017) (see, e.g., GRPO (Shao et al., 2024), DAPO (Yu et al., 2025) and (Fu et al., 2025)), or the more basic REINFORCE algorithms (Williams, 1992) (see, e.g., (Ahmadian et al., 2024; Chu et al., 2025)). Though PPO was initially proposed in actor-critic style, the critic is replaced with Monte-Carlo rollout in resource-limited or outcome-driven LLM training scenarios. Contrary to the practice in robotic and games RL (Mnih et al., 2016; Schulman et al., 2017), the fore-mentioned LLM-RL algorithms do not consider entropy regularization.

Entropy regularization in RL. Entropy-regularized RL was initially introduced in (Williams & Peng, 1991). It has been commonly used in various popular policy-based deep RL algorithms (Mnih et al., 2016; Schulman et al., 2017; Haarnoja et al., 2018) which have provided ample empirical evidence for its effectiveness in robotic and games tasks. Entropy regularization's optimization benefits have also been empirically (Ahmed et al., 2019) and theoretically (Mei et al., 2020) studied. However, it does not give notable performance gains for LLMs (see, e.g., Section 5 and (Cui et al., 2025; Klein et al., 2023)). As a result, alternative entropy control techniques are often adopted. In (Zhang et al., 2024) reshapes the reward function to regulate the policy. Or in a concurrent work (Cui et al., 2025), the algorithm clips or regulates the parts the policy update that decrease entropy too much. To our best knowledge, existing works do not answer the question of why and when entropy regularization can fail in LLM-RL, and have not uncovered the potential benefits of entropy bonus.

# 2 Preliminaries

In this section, we will first give formal definitions of some RL concepts, and then introduce several prominent existing policy optimization algorithms.

Finite-horizon Markov decision process (MDP). In LLM-RL setting, the learning task can be modeled as a finite-horizon MDP defined by a  $\mathcal{M} = \{\mathcal{S}, \mathcal{A}, \mathcal{P}, r, H\}$ , where  $\mathcal{S}$  is a finite state space (e.g., input space of the LLM),  $\mathcal{A}$  is a finite action space (e.g., LLM's vocabulary),  $\mathcal{P}(s_{t+1} = \cdot | s_t, a_t)$  is the state transition kernel, which is assumed to be deterministic in LLM tasks (e.g.,  $s_{t+1}$  is a concatenation of  $(s_t, a_t)$ ). Function  $r(s, a) \in [0, 1]$  assigns a reward to the pair (s, a). Horizon H corresponds to the max response length. An LLM-policy parameterized by  $\theta \in \mathbb{R}^d$  is denoted as  $\pi_{\theta}(a|s)$ , which assigns a probability for each token  $a \in \mathcal{A}$  given input  $s \in \mathcal{S}$ .

**RL** objectives. Given the initial time step h and state  $s_h = s$ , define the cumulative reward as

$$V_h^{\pi_\theta}(s) := \mathbb{E}_{\pi_\theta} \left[ \sum_{t=h}^{H-1} r(s_t, a_t) | s_h = s \right]$$
 (2.1)

where  $\pi_{\theta}(s_t) \coloneqq \pi_{\theta}(\cdot|s_t)$ , the expectation is taken over the trajectory  $(a_t, s_{t+1}, \dots, a_{H-1})$  where  $a_t \sim \pi_{\theta}(s_t)$  for each t. Similarly, we can define the Q-function as  $Q_h^{\pi_{\theta}}(s, a) = r(s, a) + V_{h+1}^{\pi_{\theta}}(s')$  with s' = (s, a), and the advantage function as  $A_h^{\pi_{\theta}}(s, a) = Q_h^{\pi_{\theta}}(s, a) - V_h^{\pi_{\theta}}(s)$ . Given a dataset  $\mathcal{D}$  containing input queries, the objective of RL is to maximize the expected value on  $\mathcal{D}$ :

$$\max_{\theta} V^{\pi_{\theta}}(\mathcal{D}) := \mathbb{E}_{s \sim \mathcal{D}}[V^{\pi_{\theta}}(s)] = \mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} r(s_t, a_t) \right]$$
 (2.2)

where  $V^{\pi_{\theta}}(s) = V_0^{\pi_{\theta}}(s)$ , and we omit time step subscripts for the value functions of step 0.

**Entropy-regularized RL.** Given  $\mathcal{D}$ , we can define the entropy of the policy  $\pi_{\theta}$  as

$$\mathcal{H}(\pi_{\theta}) := -\mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} \log \pi_{\theta}(a_t | s_t) \right]$$
 (2.3)

In maximum entropy RL, we optimize for the entropy regularized objective:

$$\max_{\theta} V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) := V^{\pi_{\theta}}(\mathcal{D}) + \lambda \mathcal{H}(\pi_{\theta}) = \mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} r(s_t, a_t) - \lambda \log \pi_{\theta}(a_t | s_t) \right]. \tag{2.4}$$

We can then analogously define the entropy-regularized value functions given the initial state and action s,a and initial time-step h as  $V_{h,\lambda}^{\pi_{\theta}}(s) \coloneqq \mathbb{E}_{\pi_{\theta}} \big[ \sum_{t=h}^{H-1} \big( r(s_t,a_t) - \lambda \log \pi_{\theta}(a_t|s_t) \big) \big| s_h = s \big]$  and  $Q_{h,\lambda}^{\pi_{\theta}}(s,a) \coloneqq r(s,a) + V_{h+1,\lambda}^{\pi_{\theta}}(s')$  with s' = (s,a). Then the entropy-regularized advantage function is defined as  $A_{h,\lambda}^{\pi_{\theta}}(s,a) = Q_{h,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\theta}(a|s) - V_{h,\lambda}^{\pi_{\theta}}(s)$ .

#### 2.1 POLICY-GRADIENT BASED LLM-RL ALGORITHMS

We give a brief review over some prominent policy optimization algorithms. The gradients of the objectives are essentially estimates of  $\nabla V^{\pi_{\theta}}(\mathcal{D})$ , thus making them policy-gradient based methods.

**PPO-clip family.** Given the sampling policy  $\pi_b$ , the objectives of PPO-clip algorithms (Schulman et al., 2017) can be written as

$$\mathcal{L}_{\text{clip}}(\theta) = \mathbb{E}_{s_0 \sim \mathcal{D}, \{a_t \sim \pi_{\text{b}}(s_t)\}_{t \leq H-1}} \left[ \min \left( \frac{\pi_{\theta}(a_t|s_t)}{\pi_{\text{b}}(a_t|s_t)} \hat{A}_t, \text{clip} \left( \frac{\pi_{\theta}(a_t|s_t)}{\pi_{\text{b}}(a_t|s_t)}, 1 - \epsilon_{\text{low}}, 1 + \epsilon_{\text{high}} \right) \hat{A}_t \right) \right]$$
(2.5)

where  $\hat{A}_t$  is an estimate of the advantage  $A_t^{\pi_{\theta}}(s_t, a_t)$ . GRPO uses a trajectory-level Monte-Carlo estimate of the advantage. DAPO additionally decouples the clip ratio by setting different  $\epsilon_{\text{low}}, \epsilon_{\text{high}}$  and incorporates extra sampling constraints and overlong response penalty.

**REINFORCE** with a baseline. With  $\pi_b = \pi_\theta$ , REINFORCE objective can be written as

$$\mathcal{L}_{\text{reinforce}}(\theta) = \mathbb{E}_{s_0 \sim \mathcal{D}, \{a_t \sim \pi_b(s_t)\}_{t < H-1}} \left[ \hat{A}_t \log \pi_{\theta}(a_t | s_t) \right]$$
(2.6)

where the gradient calculation w.r.t.  $\theta$  ignores  $\pi_b$ . Some recent works (Ahmadian et al., 2024; Chu et al., 2025) found simple REINFORCE can outperform PPO-type algorithms in certain settings.

## 3 A THEORY ON ENTROPY EFFECT IN POLICY GRADIENT BASED LLM-RL

In this section, we give some theoretical insights into LLM-RL training. We will show performance bounds for RL algorithms without entropy control or with conventional entropy control. We will also draw connections with some concurrent works based on our theoretical insights.

Suppose the LLM is a softmax policy, that is

$$\pi_{\theta}(a|s) = \frac{\exp(\theta_{s,a})}{\sum_{a} \exp(\theta_{s,a})}$$

where  $\theta_{s,a}$  is the logit of token a given input s. The LLM-RL algorithms without entropy regularization are generally guaranteed to converge to an  $\epsilon$ -stationary point of the RL objective  $V^{\pi_{\theta}}(\mathcal{D})$  satisfying  $\|\nabla V^{\pi_{\theta}}(\mathcal{D})\| \leq \epsilon$  (Agarwal et al., 2021; Jin et al., 2023). When doing policy optimization without regularization, (Cui et al., 2025) observes that the policy entropy quickly diminishes as performance increases, and ultimately performance saturates when entropy completely collapses. In the following result, we give some theoretical insights into this case.

**Proposition 1** (Bounds under no entropy control). Assume the policy is a softmax. Then the following two statements hold.

- (I) Policy entropy is an upper bound of the policy gradient:  $\|\nabla V^{\pi_{\theta}}(\mathcal{D})\| \leq 2\mathcal{H}(\pi_{\theta})$ .
- (II) If  $\|\nabla V^{\pi_{\theta}}(\mathcal{D})\| \leq \epsilon$ , then given any query  $s_0$  in dataset  $\mathcal{D}$ , the policy suboptimality on the query satisfies

$$V^{\pi^*}(s_0) - V^{\pi_{\theta}}(s_0) \le |\mathcal{D}| \frac{1}{C^{\pi_{\theta}}(s_0)} \epsilon$$

where  $\pi^* \in \arg \max_{\pi} V^{\pi}(\mathcal{D})$ ,  $C^{\pi_{\theta}}(s_0) := H^{-0.5} \max_{(a_0, \dots, a_{H-1}) \in \mathcal{A}_H^*(s_0)} \Pi_{t=0}^{H-1} \pi_{\theta}(a_t | s_t)$  in which  $\mathcal{A}_H^*(s_0) = \{(a_0, a_1, \dots, a_{H-1}) \in \mathcal{A}^H \mid \exists \pi^*, \Pi_{t=0}^{H-1} \pi^*(a_t | s_t) > 0\}$  is the set of all optimal responses given query  $s_0$ .

*Note*  $\|\nabla V^{\pi_{\theta}}(\mathcal{D})\|$  *is the policy gradient without entropy regularization.* 

The first bullet (I) suggests the policy entropy is an indicator of the policy stationarity, that is, a small entropy indicates a small policy gradient  $\|\nabla V^{\pi_{\theta}}(\mathcal{D})\|$  and the convergence of the policy. The second bullet (II) quantifies the actual performance of the almost stationary policy, where the reward on query  $s_0$  is bounded by  $\mathcal{O}(\epsilon/C^{\pi_{\theta}}(s_0))$ . The factor  $C^{\pi_{\theta}}(s_0)$  can be controlled (bounded away from 0) when the initial LLM and the RL algorithm can sufficiently explore the optimal response to  $s_0$ . For example, one can either use a large batch size (Klein et al., 2023) or a strong initial model (Weissmann et al., 2024) to control  $C^{\pi_{\theta}}(s_0)$ . In this case, the performance is ultimately bounded by  $\mathcal{O}(\epsilon)$ . The error  $\epsilon$  decreases with prolonged RL training, while it usually cannot decrease to 0 due to the presence of sampling noise or the advantage estimate error.

On the other hand, the maximum entropy RL optimizes the entropy-regularized reward sum  $V_{\lambda}^{\pi_{\theta}}(\mathcal{D})$  (Williams & Peng, 1991). In non-LLM deep RL tasks, this method has long been popular and can significantly outperform methods without entropy control (Mnih et al., 2016; Haarnoja et al., 2018). However, experiments (to be shown in Section 5) show that traditional entropy regularization gives weak to no gains in LLM-RL training. In the next result, we give theoretical insight into this issue.

**Proposition 2** (Bound for entropy-regularized methods). Assume the policy is a softmax. If  $\|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\| \leq \epsilon$ , then given any query  $s_0$ , the policy suboptimality on the query satisfies

$$V^{\pi^*}(s_0) - V^{\pi_{\theta}}(s_0) \le |\mathcal{D}|^2 \frac{1}{C_{\lambda}^{\pi_{\theta}}(s_0)} \frac{\epsilon^2}{2\lambda} + \underbrace{\lambda H \log \frac{|\mathcal{A}|}{|\mathcal{A}_H^*(s_0)|^{\frac{1}{H}}}}_{\text{bias}}$$

where  $C_{\lambda}^{\pi_{\theta}}(s_0)$  will be specified in the proof.

Similar conditions to Propositions 1.(II)&2 have been derived in (Mei et al., 2020) for the discounted infinite horizon MDPs, while our results hold for the finite horizon MDPs under a deterministic transition. Proposition 2 also provides a more accurate bound for the entropy bias.

Entropy regularization suffers from large bias due to immense response space with sparse optimality in LLM tasks. As compared to no entropy control case in Proposition (II), the above bound's dependence on  $\epsilon$  improves to  $\mathcal{O}(\epsilon^2/2\lambda)$ . However, this optimization benefit does not come free as a bias term is introduced. The entropy bias is  $\mathcal{O}(H\log(|\mathcal{A}|/|\mathcal{A}_H^*(s_0)|^{\frac{1}{H}}))$ , which increases with the response space size  $H\log|\mathcal{A}|$  and the sparsity of optimal responses  $\log(1/|\mathcal{A}_H^*(s_0)|)$ . The bias is especially ubiquitous in LLM-RL, where the response space is typically extremely large (hundreds of thousands tokens to choose from in each step) as compared to that in, e.g., classic control and games where the action space size and horizon are typically at the hundreds (Brockman et al., 2016; Silver et al., 2017).

To leverage the benefit of entropy regularization, it is crucial to reduce the entropy bias. In the following sections, we propose our recipe for this issue and empirically demonstrate its effectiveness.

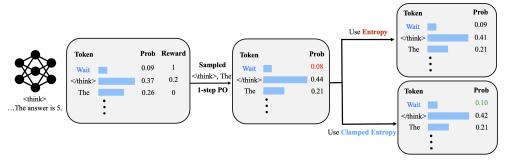

Figure 1: Policy after 1-step policy optimization (PO) with no entropy control, the traditional entropy bonus and the clamped entropy bonus, respectively. The numbers result from direct computation.

# 4 AENT: ADAPTIVE ENTROPY REGULARIZATION WITH TOKEN SPACE CLAMPING

In this section, we will first introduce the two core components of our method, and then present the AEnt algorithm.

#### 4.1 Entropy with token space clamping

Recall that maximum entropy RL maximizes  $V^{\pi_{\theta}}(\mathcal{D}) + \lambda \mathcal{H}(\pi_{\theta})$  where

$$\mathcal{H}(\pi_{\theta}) = -\sum_{t=0}^{H-1} \mathbb{E}_{s_t \sim \pi_{\theta}} \Big[ \sum_{a \in \mathcal{A}} \pi_{\theta}(a|s_t) \log \pi_{\theta}(a|s_t) \Big].$$
 (Entropy)

Entropy  $\mathcal{H}(\pi)$  is maximized by the uniform policy  $\pi_{\mathrm{uniform}}(a|s) = 1/|\mathcal{A}|$ . Maximizing the entropy pulls the LLM policy towards  $\pi_{\mathrm{uniform}}(a|s) = 1/|\mathcal{A}|$ , increasing the likelihood of low-probability actions while decreasing those of the high-probability ones. Intuitively, this helps when the optimal actions have low probabilities and are thus less likely to be sampled and reinforced. Such mechanism works well in the RL tasks where the discrete action space is small (Brockman et al., 2016). While it is extremely inefficient in LLM-RL setting since  $\mathcal{A}$  is prohibitively immense with sparse optimal tokens. Specifically, when  $1/|\mathcal{A}|$  is small, pulling  $\pi_{\theta}(a|s)$  for every  $a \in \mathcal{A}$  towards  $1/|\mathcal{A}|$  gives weak gains and produces large bias due to the large amount of non-optimal tokens in the complete token space.

To overcome this issue, we instead use a clamped entropy:

$$\begin{split} \tilde{\mathcal{H}}(\pi_{\theta}) &\coloneqq -\sum_{t=0}^{H-1} \mathbb{E}_{s_{t} \sim \pi_{b}} \Big[ \sum_{a \in \mathcal{A}(s_{t})} \tilde{\pi}_{\theta}(a|s_{t}) \log \tilde{\pi}_{\theta}(a|s_{t}) \Big] \end{aligned} \qquad \text{(Clamped entropy)} \\ \text{with } \tilde{\pi}_{\theta}(a|s) &= \frac{\exp \left(\theta_{s,a}\right)}{\sum_{a \in \mathcal{A}(s)} \exp \left(\theta_{s,a}\right)} \text{ and } \mathcal{A}(s) = \{ \text{top } (1-p) \text{ percent tokens in } \pi_{\theta}(\cdot|s) \} \end{split}$$

The clamped entropy is evaluated by a re-normalized policy  $\tilde{\pi}_{\theta}$  on a size-reduced, input-dependent token space  $\mathcal{A}(s)$ . By the theoretical insights in Section 3, regularizing on a smaller response space with denser optimality generally leads to reduced bias. With this principle, we set  $\mathcal{A}(s)$  as the the top-probability tokens set of  $\pi_{\theta}(s)$ . The intuition is that since the base models are pre-trained or fine-tuned prior to the RL phase, the bottom probability tokens are unlikely to be optimal. We find leaving them out reduces entropy-induced bias and leads to notable performance gains in LLM-RL.

To directly observe the effect of clamped entropy, we provide a numerical illustration in Figure 1. We can see that policy optimization without entropy control tends to reinforce the high-probability locally optimal tokens, while squeezing down the low-probability optimal ones that are less likely to be sampled. This creates a negative-effect loop that cannot be reversed once policy entropy collapses. On the other hand, using the clamped entropy bonus lifts up the low-probability optimal tokens. This makes them more likely to be sampled in subsequent iterations and get properly reinforced.

## 4.2 Adaptive clamped entropy control

# Algorithm 1 AEnt: Adaptive entropy regularization with token space clamping

- 1: Initialize the algorithm, including choosing  $\tilde{\mathcal{H}}_{low}$ ,  $\tilde{\mathcal{H}}_{high}$  and  $\lambda_{low}$ ,  $\lambda_{high}$ , clamping percentage p.
- 2: **for** global step k = 1 **to** K **do**
- 3: Set the sampling policy  $\pi_b$ .
- 4: Sample a batch of  $s_0$  and for each  $s_0$ , a batch of  $(a_0, s_1, a_1, \ldots, s_{H-1}, a_{H-1})$  following  $\pi_b$ .
- 5: Optimize for the batch surrogate of  $\mathcal{L}_{AEnt}(\theta; \lambda)$  w.r.t.  $\theta$ .
- 6: Adjust the clamped entropy coefficient  $\lambda$  following scheme 4.1.
- 7: end for

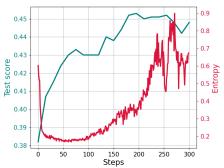

Figure 2: GRPO with a constant entropy bonus coefficient.

For entropy-regularized RL, a constant entropy coefficient  $\lambda$  is often sufficient to properly control the policy entropy in robotic and games RL (Mnih et al., 2016; Haarnoja et al., 2018). However, we observe in Figure 2 that this assumption does not necessarily hold in LLM-RL training as the entropy can change drastically in the mid of training, and the initially chosen coefficient fails. In the example, the entropy stabilizes in the early period, but starts to drastically fluctuates after step 200 while the policy performance saturates. The entropy coefficient is not adjusted to change such a trend and fails to deliver better performance promised by entropy control.

To alleviate this issue, we automatically adjust the co-

efficient during training following

$$\lambda' \leftarrow \operatorname{Proj}_{[\lambda_{\text{low}}, \lambda_{\text{high}}]} \left[ \lambda - \beta \min \left( \tilde{\mathcal{H}}(\pi_{\theta}) - \tilde{\mathcal{H}}_{\text{low}}, 0 \right) + \beta \min \left( \tilde{\mathcal{H}}_{\text{high}} - \tilde{\mathcal{H}}(\pi_{\theta}), 0 \right) \right]$$
(4.1)

where  $\beta$  is the coefficient learning rate, and  $\tilde{\mathcal{H}}_{low}$ ,  $\tilde{\mathcal{H}}_{high}$  are respectively the lower and upper limit of the (clamped) entropy. The algorithm will try to confine  $\tilde{\mathcal{H}}$  within  $[\tilde{\mathcal{H}}_{low}, \tilde{\mathcal{H}}_{high}]$  by increasing/decreasing  $\lambda$  when  $\tilde{\mathcal{H}}(\pi_{\theta})$  is lower/higher than the limits. The intuition is that when entropy is high, the coefficient should be tuned down to reduce the entropy induced bias and shift weights to greedy reward maximization, which in turn consumes entropy. While when entropy level is too low, the coefficient can be tuned up to leverage the benefits of entropy regularization. For better training stability, the entropy coefficient is also boxed in the range  $[\lambda_{low}, \lambda_{high}]$  so that large fluctuations of entropy do not lead to coefficient over-shoot. Empirically, we find that such an update rule can effectively confine the policy entropy, which can further improve reasoning efficiency by avoiding entropy and response length explosion.

## 4.3 ALGORITHM

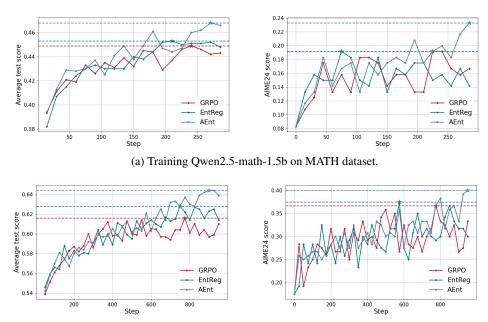

Given the current LLM policy  $\pi_{\theta}$ , we approximately maximize the following objective at each step:

$$\mathcal{L}_{AEnt}(\theta;\lambda) = \mathcal{L}_{PO}(\theta) + \lambda \tilde{\mathcal{H}}(\pi_{\theta})$$
(4.2)

where  $\mathcal{L}_{PO}(\theta)$  is a policy optimization objective of which the gradient is an ascent direction of  $V^{\pi_{\theta}}$ . Candidates of  $\mathcal{L}_{PO}$  include the objectives introduced in Section 2.1, e.g., GRPO objective is used in our tests. At each global step, we set the sampling policy  $\pi_b$  according to the choice of policy optimization objective  $\mathcal{L}_{PO}$ . For example, in PPO-type algorithms,  $\pi_b$  is set as  $\pi_{old}$  which is the policy from last global step. Given  $\pi_b$ , a batch of queries  $s_0 \sim \mathcal{D}$  are sampled, and for each query,  $\pi_b$  rolls out a batch of trajectories up to the maximum time step. With the batched samples, we can then optimize for the batch surrogate of  $\mathcal{L}_{AEnt}(\theta; \lambda)$  for several mini-epochs. At the end of each global step, the entropy coefficient is adjusted according to scheme 4.1. The whole process is summarized in Algorithm 1.

### 5 EXPERIMENTS

In this section, we conduct experiments to verify the effectiveness of our method.

(b) Training DeepSeek-R1-distilled-Qwen-1.5b on a subset of OpenR1-math dataset.

Figure 3: Test score comparison (see Figure 4 for more training metrics).

Table 1: Test scores by benchmark, where we evaluate the model with the highest average test score trained by each algorithm. Here (a), (b) indicates the two settings described in 5.1. **Bold** numbers indicate the best performance one on the benchmark.

# 5.1 Training details

Models, training datasets and baselines. The algorithms are tested in two training settings: (a) we train the Qwen2.5-math-1.5b base model on the MATH dataset (Hendrycks et al., 2021), which contains 7500 math problems with various difficulties and covers multiple mathematical areas; (b) we also train the DeepSeek-R1-distilled-Qwen-1.5b (DeepSeek-AI, 2025) model on 40k verifiable queries from the OpenR1-math (Open-R1, 2025) dataset, which is derived from Numina-math dataset (Li et al., 2024). We compare our algorithm with GRPO and the conventional entropy regularization method which we call EntReg, where the GRPO objective is augmented with the original entropy bonus used in (Mnih et al., 2016; Schulman et al., 2017).

**Evaluation.** For performance comparison, we evaluate models on the AIME 2024, MATH-Hard test split, MATH-500, AMC23, MinervaMath (Lewkowycz et al., 2022) and OlympiadBench (He et al., 2024). We estimate the test score by averaging 4 tries per query on all benchmarks. The test-time generation temperature is 0.6, top-p is 0.95 and top-k is 20.

**Hyper-parameter settings.** The tests are based on the verl framework (Sheng et al., 2025)<sup>1</sup>. When training Qwen2.5-math-1.5b base model on the MATH dataset, we use AdamW optimizer with a learning rate of  $2 \times 10^{-6}$ . We set the max response length as 3072. We use a batch size of 512, and for each query we roll out 16 responses with default sampling parameters (top-p and temperature

<sup>&</sup>lt;sup>1</sup>The code will be released as soon as an internal mandatory pre-open-source review is completed.

(b) Training DeepSeek-R1-distilled-Qwen-1.5b on a subset of OpenR1-math dataset.

Figure 4: Entropy and response length trend (see also Figure 3 for test score comparison).

set as 1). For AEnt, we use the GRPO loss as  $\mathcal{L}_{PO}$ . We use a clamping percentage p=0.33, and set  $\tilde{\mathcal{H}}_{low}=0.13$  and  $\tilde{\mathcal{H}}_{high}=0.24$ . We use an initial entropy coefficient of 0.002, and start updating the coefficient from the third epoch with a learning rate of 0.002. We clip the coefficient in between 0.006 and 0.009. For EntReg method, we use the traditional entropy bonus with a fixed entropy coefficient of 0.002. When training DeepSeek-R1-distilled-Qwen model on the OpenR1-math dataset, we use a learning rate of  $1\times10^{-6}$ , a max response length of 7168, a batch size of 256 and for each query we roll out 8 responses. We use p=0.25,  $\tilde{\mathcal{H}}_{low}=0.35$  and  $\tilde{\mathcal{H}}_{high}=0.62$ , an initial coefficient of  $3\times10^{-4}$ , and start updating the coefficient from the second epoch with a learning rate of  $10^{-4}$ . We clip the coefficient in between  $4\times10^{-5}$  and 0.001.

#### 5.2 Performance analysis

We report the test performance in Table 1 and Figures 3 & 4. It is observed AEnt outperforms the baselines on average, and on 5 out of the 6 benchmarks across the two different experimental settings.

An observation on the test score and the entropy trend. An interesting observation from Figures 4a is that after around 175 steps (collapse time), the policy entropy of GRPO largely depletes and the entropy of EntReg starts to drastically fluctuate, while AEnt's policy entropy is kept stable. Then one can observe from Figure 3a that the test score of GRPO and EntReg saturates around the same step, while the score of AEnt continues to improve and surpasses the baselines past the collapse time. This observation is consistent with our intuition and theoretical analysis: after GRPO's entropy collapse, its policy becomes concentrated on few paths and no new information can be gained in the sampling process, ultimately leading to the stagnancy of the learning process. This is predicted by Proposition (I) that the policy will become stationary after entropy depletion.

#### 5.3 ABLATION STUDIES

In this section, we conduct ablation studies on our algorithm.

**Adaptive coefficient stabilizes training.** In Figure 5, we compare the performance of adaptive coefficient vs constant coefficient. The test performance is similar for the two methods in this particular experiment. However, adaptive coefficient leads to a significant advantage on reasoning efficiency by delivering more compact responses while not sacrificing accuracy. In the third plot of

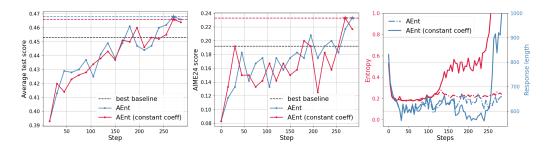

Figure 5: AEnt with adaptive entropy coefficient vs with a constant coefficient. The score in this test is similar. Adaptive coefficient better controls the response length and the policy entropy.

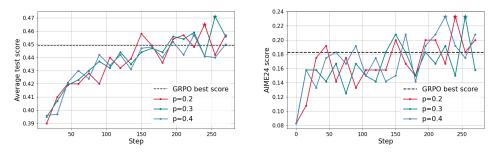

Figure 6: Comparison of different clamping percentage p.

Figure 6, constant coefficient fails to stabilize policy entropy in the mid of training, which results in the entropy blow up. We observe a positive correlation between entropy and response length in this case, where a exploding entropy leads to repeated reasoning patterns that do not increase the test scores. On the other hand, the adaptive coefficient successfully prevents the entropy and response length from blowing up.

Analysis of the entropy clamping percentage p. In Figure 6, we compare the algorithmic performance under different choice of clamping percentage p. It can be observed that a too large or too small p can result in non-optimal gains. Intuitively, the percentage p decides the size of the clamped space  $\mathcal{A}(s)$ , where a larger p leads to more aggressive clamping and less tokens taken into account during entropy calculation. This would smooth the LLM policy on a more compact space, reducing the bias induced by entropy maximization while running the risk to leave out valuable tokens. In this sense, it is reasonable to try to maximize p until the performance drops, which is also suggested by our reported results. Despite the fact the AEnt's performance is affected by the choice of p, its advantage over the baselines is somewhat robust to the choice. It can be observed from Figure 6 that AEnt outperforms the baselines with different choices of p.

# 6 CONCLUSION AND FUTURE WORK

In this work, we showed that entropy regularization suffers from large bias in LLM-RL training. As a remedy of this issue, we propose an entropy control method that utilizes a clamped entropy bonus with an automatically adjusted coefficient. We show that AEnt consistently outperforms competitive baselines across multiple benchmarks. We believe AEnt can demonstrate more significant advantages if tested on larger models with more compute. In this work, we did not include a theoretical analysis of the clamped entropy. In addition, we believe the choice of the clamped space  $\mathcal{A}(s)$  is crucial to the algorithm's effectiveness, and finding a better choice can potentially yield significant performance gains. We leave these studies for future work.

#### A APPENDIX

#### A.1 PRELIMINARY LEMMAS

**Lemma 1** (Entropy gradient). For the softmax policy, we have

$$\nabla \mathcal{H}(\pi_{\theta}) = -\mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_h|s_h) \sum_{t=h}^{H-1} \log \pi_{\theta}(a_t|s_t) \right]$$
(A.1)

Proof. Starting from the definition of entropy, we can expand the expectation and write

$$\mathcal{H}(\pi_{\theta}) = -\sum_{s_{0}, a_{0}, \dots, a_{H-1}} \mathbb{P}(s_{0}, a_{0}, \dots, a_{H-1} | \pi_{\theta}) \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t} | s_{t})$$

$$= -\sum_{s_{0}, a_{0}, \dots, a_{H-1}} \mathbb{P}(s_{0}) \pi_{\theta}(a_{0} | s_{0}) \dots \pi_{\theta}(a_{H-1} | s_{H-1}) \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t} | s_{t})$$
(A.2)

where in the first equality, the expectation is only taken over  $s_0$  and the action sequence since the transition is a deterministic in our LLM setting. Then the gradient of the entropy is given by

$$\nabla \mathcal{H}(\pi_{\theta}) = -\sum_{s_{0}, a_{0}, \dots, a_{H-1}} \mathbb{P}(s_{0}) \Pi_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h}) \nabla \left(\sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t}|s_{t})\right)$$

$$-\sum_{s_{0}, a_{0}, \dots, a_{H-1}} \mathbb{P}(s_{0}) \nabla \left(\Pi_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h})\right) \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t}|s_{t})$$
(A.3)

For the first term in the RHS of equation A.3, we have

$$\sum_{s_{0},a_{0},...,a_{H-1}} \mathbb{P}(s_{0}) \Pi_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h}) \nabla \left( \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t}|s_{t}) \right) = \sum_{s_{0},...,a_{H-1}} \mathbb{P}(s_{0}) \nabla \left( \Pi_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h}) \right)$$

$$= \sum_{s_{0}} \mathbb{P}(s_{0}) \nabla \left( \sum_{a_{0}...a_{H-1}} \Pi_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h}) \right)$$

$$= \sum_{s_{0}} \mathbb{P}(s_{0}) \nabla 1 = 0$$
(A.4)

For the second term in the RHS of equation A.3, we have

$$\sum_{s_{0},a_{0},...,a_{H-1}} \mathbb{P}(s_{0}) \nabla \left( \prod_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h}) \right) \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t}|s_{t})$$

$$= \sum_{s_{0},a_{0},...,a_{H-1}} \mathbb{P}(s_{0}) \prod_{h=0}^{H-1} \pi_{\theta}(a_{h}|s_{h}) \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t}|s_{t})$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=0}^{H-1} \log \pi_{\theta}(a_{t}|s_{t}) \right]$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=1}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=0}^{h-1} \log \pi_{\theta}(a_{t}|s_{t}) \right] + \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=h}^{H-1} \log \pi_{\theta}(a_{t}|s_{t}) \right]$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=1}^{H-1} \mathbb{E}_{a_{h} \sim \pi_{\theta}(s_{h})} \left[ \nabla \log \pi_{\theta}(a_{h}|s_{h}) |s_{h} \right] \sum_{t=0}^{h-1} \log \pi_{\theta}(a_{t}|s_{t}) \right]$$

$$+ \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=h}^{H-1} \log \pi_{\theta}(a_{t}|s_{t}) \right]$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=h}^{H-1} \log \pi_{\theta}(a_{t}|s_{t}) \right]$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_{h}|s_{h}) \sum_{t=h}^{H-1} \log \pi_{\theta}(a_{t}|s_{t}) \right]$$

$$(A.5)$$

where the second last equality follows from the towering property of the expectation, and the last equality follows from the fact that for any s, we have

$$\mathbb{E}_{a \sim \pi_{\theta}(s)} \left[ \nabla \log \pi_{\theta}(a|s) | s \right] = \sum_{a} \pi_{\theta}(a|s) \nabla \log \pi_{\theta}(a|s)$$

$$= \sum_{a} \nabla \pi_{\theta}(a|s)$$

$$= \nabla \sum_{a} \pi_{\theta}(a|s) = \nabla 1 = 0 \tag{A.6}$$

Substituting equation A.4 and equation A.5 into equation A.3 yields

$$\nabla \mathcal{H}(\pi_{\theta}) = -\mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_h|s_h) \sum_{t=h}^{H-1} \log \pi_{\theta}(a_t|s_t) \right]$$
(A.7)

This completes the proof.

**Lemma 2.** Given any  $h \in \{0, 1, ..., H-1\}$  and some baseline functions  $b_h^{\pi_\theta} : \mathcal{S} \mapsto \mathbb{R}$ , we have for any policy  $\pi_\theta$  that:

$$\mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_h|s_h) b_h^{\pi_{\theta}}(s_h) \right] = 0 \tag{A.8}$$

where the expectation is taken over  $(s_0 \sim \mathcal{D}, a_0, \dots, a_{H-1})$  generated under policy  $\pi_{\theta}$ .

Proof. We have

$$\mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \nabla \log \pi_{\theta}(a_h | s_h) b_h^{\pi_{\theta}}(s_h) \right]$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{h=0}^{H-1} \mathbb{E}_{a_h \sim \pi_{\theta}(s_h)} \left[ \nabla \log \pi_{\theta}(a_h | s_h) \right] b_h^{\pi_{\theta}}(s_h) \right] = 0$$
(A.9)

which follows from the towering property of the expectation and equation A.6.

**Lemma 3** (Entropy regularized softmax policy gradient). If the policy is a softmax, we have

$$\nabla_{\theta_{s,a}} V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s) \pi_{\theta}(a|s) A_{t,\lambda}^{\pi_{\theta}}(s,a). \tag{A.10}$$

where  $\mathbb{P}_t^{\pi_{\theta}}(s)$  is the shorthand notation of  $\mathbb{P}(s_t = s | \pi_{\theta})$ , which is the probability of reaching state s at time step t given policy  $\pi_{\theta}$ .

*Proof.* By the policy gradient theorem (Sutton et al., 1999) and its adaptation to the finite-horizon setting (see, e.g., (Klein et al., 2023)), we have

$$\nabla V^{\pi_{\theta}}(\mathcal{D}) = \mathbb{E}_{s_0 \sim \mathcal{D}, a_t \sim \pi_{\theta}(s_t)} \Big[ \sum_{t=0}^{H-1} \nabla \log \pi_{\theta}(a_t|s_t) Q_t^{\pi_{\theta}}(s_t, a_t) \Big]. \tag{A.11}$$

The above equality combined with the entropy gradient given in Lemma 1 yields

$$\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) + \lambda \nabla \mathcal{H}(\pi_{\theta})$$

$$= \mathbb{E}_{\pi_{\theta}} \Big[ \sum_{t=0}^{H-1} \nabla \log \pi_{\theta}(a_{t}|s_{t}) \big( Q_{t}^{\pi_{\theta}}(s_{t}, a_{t}) - \lambda \sum_{i=t}^{H-1} \log \pi_{\theta}(a_{i}|s_{i}) \big) \Big]$$

$$= \mathbb{E}_{\pi_{\theta}} \Big[ \sum_{t=0}^{H-1} \nabla \log \pi_{\theta}(a_{t}|s_{t}) \big( Q_{t,\lambda}^{\pi_{\theta}}(s_{t}, a_{t}) - \lambda \log \pi_{\theta}(a_{t}|s_{t}) \big) \Big]. \tag{A.12}$$

The above equality gives the policy gradient formula with the Q-function. It can also be rewritten with the advantage functions. By Lemma 2, we have

$$\mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} V_{t,\lambda}^{\pi_{\theta}}(s_t) \nabla \log \pi_{\theta}(a_t|s_t) \right] = 0. \tag{A.13}$$

Using equation A.13 in equation A.12 gives

$$\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} \nabla \log \pi_{\theta}(a_{t}|s_{t}) \left( Q_{t,\lambda}^{\pi_{\theta}}(s_{t}, a_{t}) - \lambda \log \pi_{\theta}(a_{t}|s_{t}) - V_{t,\lambda}^{\pi_{\theta}}(s_{t}) \right) \right]$$

$$= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} \nabla \log \pi_{\theta}(a_{t}|s_{t}) A_{t,\lambda}^{\pi_{\theta}}(s_{t}, a_{t}) \right]$$
(A.14)

which follows from the definition of the entropy-regularized advantage function. We can also rewrite the policy gradient formula in equation A.14 with respect to the state marginal distribution as follows:

$$\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \mathbb{E}_{s_{0} \sim \mathcal{D}, a_{t} \sim \pi_{\theta}(s_{t})} \left[ \sum_{t=0}^{H-1} \nabla \log \pi_{\theta}(a_{t}|s_{t}) A_{t,\lambda}^{\pi_{\theta}}(s_{t}, a_{t}) \right]$$

$$= \sum_{t=0}^{H-1} \mathbb{E}_{s \sim \mathbb{P}_{t}^{\pi_{\theta}}, a \sim \pi_{\theta}(s)} \left[ \nabla \log \pi_{\theta}(a|s) A_{t,\lambda}^{\pi_{\theta}}(s, a) \right]$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \pi_{\theta}(a|s) \nabla \log \pi_{\theta}(a|s) A_{t,\lambda}^{\pi_{\theta}}(s, a)$$
(A.15)

Under the softmax policy, we have  $\nabla_{\theta_{\bar{s},\bar{a}}} \log \pi_{\theta}(a|s) = \mathbf{1}_{s=\bar{s}} (\mathbf{1}_{a=\bar{a}} - \pi_{\theta}(\bar{a}|\bar{s}))$ . Then the elementwise policy gradient is

$$\nabla_{\theta_{\bar{s},\bar{a}}} V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \pi_{\theta}(a|s) \mathbf{1}_{s=\bar{s}} \Big( \mathbf{1}_{a=\bar{a}} - \pi_{\theta}(\bar{a}|\bar{s}) \Big) A_{t,\lambda}^{\pi_{\theta}}(s,a)$$

$$= \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(\bar{s}) \sum_{a} \pi_{\theta}(a|\bar{s}) \Big( \mathbf{1}_{a=\bar{a}} - \pi_{\theta}(\bar{a}|\bar{s}) \Big) A_{t,\lambda}^{\pi_{\theta}}(\bar{s},a)$$

$$= \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(\bar{s}) \pi_{\theta}(\bar{a}|\bar{s}) A_{t,\lambda}^{\pi_{\theta}}(\bar{s},\bar{a}). \tag{A.16}$$

where the last inequality is due to  $\mathbb{E}_{a \sim \pi_{\theta}(s)}[A_{t,\lambda}^{\pi_{\theta}}(s,a)] = 0$  following the definition of the value functions.

**Lemma 4** (Performance difference lemma). We have for any  $h \in \{0, 1, ..., H-1\}$  and state  $s \in S$ , the performance difference between any two policies  $\pi$  and  $\pi'$  is

$$V_h^{\pi}(s) - V_h^{\pi'}(s) = \mathbb{E}_{\pi} \Big[ \sum_{t=h}^{H-1} A_t^{\pi'}(s_t, a_t) | s_h = s \Big]. \tag{A.17}$$

Proof. We have

$$V_{h}^{\pi}(s) - V_{h}^{\pi'}(s)$$

$$= \mathbb{E}_{\pi} \Big[ \sum_{t=h}^{H-1} r(s_{t}, a_{t}) | s_{h} = s \Big] - V_{h}^{\pi'}(s)$$

$$= \mathbb{E}_{\pi} \Big[ \sum_{t=h}^{H-1} r(s_{t}, a_{t}) + \sum_{t=h}^{H-2} V_{t, \lambda}^{\pi'}(s_{t+1}) - \sum_{t=h}^{H-2} V_{t, \lambda}^{\pi'}(s_{t+1}) | s_{h} = s \Big] - V_{h}^{\pi'}(s)$$

$$= \mathbb{E}_{\pi} \Big[ \sum_{t=h}^{H-1} Q_{t, \lambda}^{\pi'}(s_{t}, a_{t}) - \sum_{t=h}^{H-1} V_{t, \lambda}^{\pi'}(s_{t}) | s_{h} = s \Big]$$

$$= \mathbb{E}_{\pi} \Big[ \sum_{t=h}^{H-1} A_{t}^{\pi'}(s_{t}, a_{t}) | s_{h} = s \Big]$$
(A.18)

This completes the proof.

# A.2 PROOF OMITTED IN SECTION 3

## A.2.1 PROOF OF PROPOSITION 1

*Proof.* We start with proving the first bullet. Denote the entropy of  $\pi_{\theta}(\cdot|s)$  as

$$\mathcal{H}(\pi(\cdot|s)) = -\sum_{a} \pi_{\theta}(a|s) \log \pi_{\theta}(a|s)$$
(A.19)

Since  $1 - x \le -\log x$  for  $0 < x \le 1$ , we have

$$\mathcal{H}(\pi(\cdot|s)) \ge \sum_{a} \pi_{\theta}(a|s)(1 - \pi_{\theta}(a|s)) \tag{A.20}$$

Viewing  $\pi_{\theta}(\cdot|s)$  as a vector in  $\Delta^{|\mathcal{A}|}$ , it is known that the softmax Jacobian can be written as

$$\frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} = \operatorname{Diag}(\pi_{\theta}(\cdot|s)) - \pi_{\theta}(\cdot|s)\pi_{\theta}(\cdot|s)^{\top}$$
(A.21)

Then we have

$$\left\| \frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} \right\| \leq \left\| \frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} \right\|_{F}$$

$$\leq \sum_{a} \left( \pi_{\theta}(a|s) \left( 1 - \pi_{\theta}(a|s) \right) + \pi_{\theta}(a|s) \sum_{a'} \pi_{\theta}(a'|s) \right)$$

$$= 2 \sum_{a} \pi_{\theta}(a|s) \left( 1 - \pi_{\theta}(a|s) \right)$$

$$\leq 2 \mathcal{H}(\pi_{\theta}(\cdot|s)) \tag{A.22}$$

By equation A.15 in Lemma 3, we have

$$\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \pi_{\theta}(a|s) \nabla \log \pi_{\theta}(a|s) A_{t,\lambda}^{\pi_{\theta}}(s,a)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \nabla \pi_{\theta}(a|s) A_{t,\lambda}^{\pi_{\theta}}(s,a)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \frac{\partial \pi_{\theta}(a|s)}{\partial \theta_{s,\cdot}} A_{t,\lambda}^{\pi_{\theta}}(s,a)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} A_{t,\lambda}^{\pi_{\theta}}(s,\cdot)$$
(A.23)

where the third equality is due to  $\frac{\partial \pi_{\theta}(a|s)}{\partial \theta_{s',\cdot}} = 0$  if  $s' \neq s$ . Then we have

$$\|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\| \leq \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \left\| \frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} \right\|$$

$$\leq 2 \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \mathcal{H}(\pi_{\theta}(\cdot|s))$$

$$= 2\mathcal{H}(\pi_{\theta}) \tag{A.24}$$

where the last inequality is due to the definition of the policy entropy:

$$\mathcal{H}(\pi_{\theta}) = -\mathbb{E}_{\pi_{\theta}} \left[ \sum_{t=0}^{H-1} \log \pi_{\theta}(a_t|s_t) \middle| s_0 \sim \mathcal{D} \right]$$
$$= -\sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_t^{\pi_{\theta}}(s) \sum_{a} \pi_{\theta}(a|s) \log \pi_{\theta}(a|s)$$
(A.25)

This completes the proof of the first bullet.

Next we provide the proof of the second bullet. Let  $\pi^* \in \arg\max_{\pi} V^{\pi}(\mathcal{D})$  be any deterministic optimal policy. Given any  $s_0 \sim \mathcal{D}$ , let  $s_h^*, a_h^*$  be a state-action pair generated by  $\pi^*$  up to time step h, e.g.,  $a_h^* = \pi^*(s_h^*)$ . We write  $s_0^* = s_0$ .

Given any  $s_0$ , we have

$$\|\nabla V^{\pi_{\theta}}(\mathcal{D})\| \ge \left(\sum_{h=0}^{H-1} \left(\nabla_{s_{h}^{*}, a_{h}^{*}} V^{\pi_{\theta}}(\mathcal{D})\right)^{2}\right)^{0.5}$$

$$\ge \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \left|\nabla_{s_{h}^{*}, a_{h}^{*}} V^{\pi_{\theta}}(\mathcal{D})\right|$$

$$= \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s_{h}^{*}) \pi_{\theta}(a_{h}^{*}|s_{h}^{*}) \left|A_{t}^{\pi_{\theta}}(s_{h}^{*}, a_{h}^{*})\right|$$
(A.26)

where the second inequality follows from Cauchy-Schwartz inequality, and the equality follows from the softmax policy gradient derived in Lemma 3.

Notice that the policy is an auto-regressive LLM and the transition is deterministic with  $\mathbb{P}(s_{t+1} = (s_t, a_t)|s_t, a_t) = 1$ , we will have  $\mathbb{P}_t^{\pi_\theta}(s_h^*) = 0$  for any  $t \neq h$ . Using this fact in equation A.26

$$\|\nabla V^{\pi_{\theta}}(\mathcal{D})\| \ge \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \mathbb{P}_{h}^{\pi_{\theta}}(s_{h}^{*}) \pi_{\theta}(a_{h}^{*}|s_{h}^{*}) |A_{h}^{\pi_{\theta}}(s_{h}^{*}, a_{h}^{*})|$$
(A.27)

Continuing from equation A.27,

$$\begin{split} &\|\nabla V^{\pi_{\theta}}(\mathcal{D})\|\\ &\geq \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \mathbb{P}_{h}^{\pi_{\theta}}(s_{h}^{*})\pi_{\theta}(a_{h}^{*}|s_{h}^{*})|A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})|\\ &= \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \frac{\mathbb{P}_{h}^{\pi_{\theta}}(s_{h}^{*})\pi_{\theta}(a_{h}^{*}|s_{h}^{*})}{\mathbb{P}_{h}^{\pi^{*}}(s_{h}^{*})\pi^{*}(a_{h}^{*}|s_{h}^{*})} \mathbb{P}_{h}^{\pi^{*}}(s_{h}^{*})\pi^{*}(a_{h}^{*}|s_{h}^{*})|A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})|\\ &= \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \frac{\mathbb{P}_{h}^{\pi_{\theta}}(s_{h}^{*})\pi_{\theta}(a_{h}^{*}|s_{h}^{*})}{\mathbb{P}(s_{0})\pi^{*}(a_{0}^{*}|s_{0}^{*})\pi^{*}(a_{1}^{*}|s_{1}^{*})\dots\pi^{*}(a_{h}^{*}|s_{h}^{*})} \mathbb{P}_{h}^{\pi^{*}}(s_{h}^{*})\pi^{*}(a_{h}^{*}|s_{h}^{*})|A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})|\\ &= \frac{|\mathcal{D}|}{\sqrt{H}} \sum_{h=0}^{H-1} \mathbb{P}_{h}^{\pi_{\theta}}(s_{h}^{*})\pi_{\theta}(a_{h}^{*}|s_{h}^{*})\mathbb{P}_{h}^{\pi^{*}}(s_{h}^{*})\pi^{*}(a_{h}^{*}|s_{h}^{*})|A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})| \end{aligned} \tag{A.28}$$

where the second last inequality follows from the definition of  $\mathbb{P}_h^{\pi}(s_h)$ , and the last inequality follows from the fact that  $\pi^*$  is defined as a deterministic optimal policy, yielding

$$\mathbb{P}(s_0)\pi^*(a_0^*|s_0^*)\pi^*(a_1^*|s_1^*)\dots\pi^*(a_h^*|s_h^*) = \mathbb{P}(s_0) = \frac{1}{|\mathcal{D}|}.$$
 (A.29)

Continuing from equation A.28, we have

$$\|\nabla V^{n\theta}(\mathcal{D})\|$$

$$\geq \left(\min_{h\in\{0,1,\dots,H-1\}} \mathbb{P}_{h}^{\pi_{\theta}}(s_{h}^{*})\pi_{\theta}(a_{h}^{*}|s_{h}^{*})\right) \frac{|\mathcal{D}|}{\sqrt{H}} \sum_{h=0}^{H-1} \mathbb{P}_{h}^{\pi^{*}}(s_{h}^{*})\pi^{*}(a_{h}^{*}|s_{h}^{*})A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})$$

$$= \Pi_{h=0}^{H-1}\pi_{\theta}(a_{h}^{*}|s_{h}^{*}) \frac{1}{\sqrt{H}} \sum_{h=0}^{H-1} \mathbb{P}_{h}^{\pi^{*}}(s_{h}^{*})\pi^{*}(a_{h}^{*}|s_{h}^{*})A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})$$

$$\geq \frac{1}{\sqrt{H}|\mathcal{D}|} \Pi_{h=0}^{H-1}\pi_{\theta}(a_{h}^{*}|s_{h}^{*})\mathbb{E}_{\pi^{*}} \left[A_{h}^{\pi_{\theta}}(s_{h}^{*},a_{h}^{*})|s_{0}\right]$$

$$\geq \frac{1}{\sqrt{H}|\mathcal{D}|} \Pi_{h=0}^{H-1}\pi_{\theta}(a_{h}^{*}|s_{h}^{*}) \left(V^{\pi^{*}}(s_{0}) - V^{\pi_{\theta}}(s_{0})\right). \tag{A.30}$$

Note that this inequality holds for any trajectory  $(s_0, a_0^*, a_1^*, \dots, a_{H-1}^*)$  generated by any deterministic optimal policy  $\pi^*$ . Then we have

$$\|\nabla V^{\pi_{\theta}}(\mathcal{D})\| \ge \frac{1}{\sqrt{H}|\mathcal{D}|} C^{\pi_{\theta}}(s_0) \Big( V^{\pi^*}(s_0) - V^{\pi_{\theta}}(s_0) \Big)$$
(A.31)

where 
$$C^{\pi_{\theta}}(s_0) = \max_{(a_0, \dots, a_{H-1}) \in \mathcal{A}_H^*(s_0)} \Pi_{t=0}^{H-1} \pi_{\theta}(a_t | s_t)$$
 with  $\mathcal{A}_H^*(s_0) = \{(a_0, a_1, \dots, a_{H-1}) \in \mathcal{A}^H \mid \exists \pi^* \in \arg \max_{\pi} V^{\pi}(\mathcal{D}), \Pi_{t=0}^{H-1} \pi^*(a_t | s_t) > 0\}.$ 

#### A.3 Proof of Proposition 2

Proposition 2 can be proven by combining Lemma 5 and Lemma 6.

Lemma 5. It holds that

$$V^{\pi^*}(s_0) - V^{\pi_{\theta}}(s_0) \le V_{\lambda}^{\pi_{\lambda}^*}(s_0) - V_{\lambda}^{\pi_{\theta}}(s_0) + \lambda H \log \frac{|\mathcal{A}|}{|\mathcal{A}_H^*(s_0)|^{\frac{1}{H}}}$$
(A.32)

where  $\pi_{\lambda}^* = \arg\max_{\pi} V_{\lambda}^{\pi}(\mathcal{D})$ , and recall  $\pi^* \in \arg\max_{\pi} V^{\pi}(\mathcal{D})$ . Here  $\mathcal{A}_{H}^*(s_0) = \{(a_0, a_1, \ldots, a_{H-1}) \in \mathcal{A}^H \mid \exists \pi^*, \Pi_{t=0}^{H-1} \pi^*(a_t | s_t) > 0\}$  is the set of all optimal responses given query  $s_0$ .

*Proof.* Define  $\mathcal{H}(\pi|s_0)$  as

$$\mathcal{H}(\pi|s_0) = -\mathbb{E}_{\pi} \left[ \sum_{t=0}^{H-1} \log \pi(a_t|s_t) |s_0 \right]$$
 (A.33)

For any  $\pi^* \in \arg \max_{\pi} V^{\pi}(\mathcal{D})$ , by the optimality of  $\pi^*_{\lambda}$  we have

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_{0}) - V_{\lambda}^{\pi_{\theta}}(s_{0}) \ge V_{\lambda}^{\pi^{*}}(s_{0}) - V_{\lambda}^{\pi_{\theta}}(s_{0})$$

$$= V^{\pi^{*}}(s_{0}) - V^{\pi_{\theta}}(s_{0}) + \lambda(\mathcal{H}(\pi^{*}|s_{0}) - \mathcal{H}(\pi_{\theta}|s_{0}))$$
(A.34)

where the equality follows from the definition of  $V_{\lambda}^{\pi}(s_0)$ . Then we have

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_{0}) - V_{\lambda}^{\pi_{\theta}}(s_{0})$$

$$\geq V^{\pi^{*}}(s_{0}) - V^{\pi_{\theta}}(s_{0}) + \lambda \left( \max_{\pi^{*} \in \arg\max_{\pi} V^{\pi}(\mathcal{D})} \mathcal{H}(\pi^{*}|s_{0}) - \mathcal{H}(\pi_{\theta}|s_{0}) \right)$$
(A.35)

Notice that

$$\max_{\pi^*} \mathcal{H}(\pi^*|s_0) = \max_{\pi^*} -\mathbb{E}_{\pi^*} \left[ \sum_{t=0}^{H-1} \log \pi^*(a_t|s_t) |s_0 \right] 
= \max_{\pi^*} - \sum_{a_0, \dots, a_{H-1} \in \mathcal{A}_H^*(s_0)} \Pi_{t=0}^{H-1} \pi^*(a_t|s_t) \left[ \log \Pi_{t=0}^{H-1} \pi^*(a_t|s_t) \right] 
\leq \max_{\mathbb{P} \in \Delta(\mathcal{A}_H^*(s_0))} - \sum_{\tau \in \mathcal{A}_H^*(s_0)} \mathbb{P}(\tau) \left[ \log \mathbb{P}(\tau) \right] 
= - \sum_{\tau \in \mathcal{A}_H^*(s_0)} \frac{1}{|\mathcal{A}_H^*(s_0)|} \log \frac{1}{|\mathcal{A}_H^*(s_0)|} 
= \log |\mathcal{A}_H^*(s_0)|.$$
(A.36)

where in the third inequality,  $\Delta(\mathcal{A}_H^*(s_0))$  denotes the probability simplex on  $\mathcal{A}_H^*(s_0)$ . Additionally, it is known that

$$\mathcal{H}(\pi_{\theta}|s_0) \le \max_{\pi} \mathcal{H}(\pi|s_0) = H\log|\mathcal{A}| \tag{A.37}$$

Substituting equation A.36 and equation A.37 into equation A.35 yields

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_{0}) - V_{\lambda}^{\pi_{\theta}}(s_{0}) \ge V^{\pi^{*}}(s_{0}) - V^{\pi_{\theta}}(s_{0}) + \lambda H \log \frac{|\mathcal{A}|}{|\mathcal{A}_{H}^{*}(s_{0})|^{\frac{1}{H}}}$$
(A.38)

which completes the proof.

Next we present the performance bound under entropy regularization. The derivation is adapted from (Mei et al., 2020, Lemma 15) for the LLM setting modeled as finite-horizon MDPs with a deterministic state transition.

Lemma 6. Assume the policy is a softmax. Then it holds that

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_{0}) - V_{\lambda}^{\pi_{\theta}}(s_{0}) \leq \frac{1}{2\lambda} \frac{|\mathcal{D}|^{2}}{C_{\lambda}^{\pi_{\theta}}(s_{0})} \|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\|^{2}$$
(A.39)

where and  $C_{\lambda}^{\pi_{\theta}}(s_0)$  is specified in the proof.

*Proof.* The performance gap can be bounded as

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_{0}) - V_{\lambda}^{\pi_{\theta}}(s_{0})$$

$$= \mathbb{E}_{\pi_{\lambda}^{*}} \Big[ \sum_{t=0}^{H-1} r(s_{t}, a_{t}) - \lambda \log \pi_{\lambda}^{*}(a_{t}|s_{t}) + V_{t,\lambda}^{\pi_{\theta}}(s_{t}) - V_{t,\lambda}^{\pi_{\theta}}(s_{t})|s_{0} \Big] - V_{t,\lambda}^{\pi_{\theta}}(s_{0})$$

$$= \mathbb{E}_{\pi_{\lambda}^{*}} \Big[ \sum_{t=0}^{H-1} r(s_{t}, a_{t}) - \lambda \log \pi_{\lambda}^{*}(a_{t}|s_{t}) + V_{t+1,\lambda}^{\pi_{\theta}}(s_{t+1}) - V_{t,\lambda}^{\pi_{\theta}}(s_{t})|s_{0} \Big]$$

$$= \mathbb{E}_{\pi_{\lambda}^{*}} \Big[ \sum_{t=0}^{H-1} Q_{t,\lambda}^{\pi_{\theta}}(s_{t}, a_{t}) - \lambda \log \pi_{\lambda}^{*}(a_{t}|s_{t}) - V_{t,\lambda}^{\pi_{\theta}}(s_{t})|s_{0} \Big]$$

$$= \sum_{t=0}^{H-1} \mathbb{E}_{s \sim \mathbb{P}_{t}^{\pi_{\lambda}^{*}}(\cdot|s_{0})} \Big[ \mathbb{E}_{a \sim \pi_{\lambda}^{*}(s)} \Big[ Q_{t,\lambda}^{\pi_{\theta}}(s, a) - \lambda \log \pi_{\lambda}^{*}(a|s) \Big] - V_{t,\lambda}^{\pi_{\theta}}(s) \Big]$$
(A.40)

where  $\mathbb{P}^{\pi^*_{\lambda}}_t(\cdot|s_0) = \mathbb{P}(s_t = \cdot|s_0, \pi^*_{\lambda})$  is the probability distribution of  $s_t$  under policy  $\pi^*_{\lambda}$  given the initial state  $s_0$ . The second last equality uses the definition of  $Q^{\pi_{\theta}}_{t,\lambda}$  that  $Q^{\pi_{\theta}}_{t,\lambda}(s_t, a_t) = r(s_t, a_t) + V^{\pi_{\theta}}_{t+1,\lambda}(s_{t+1})$  with  $s_{t+1} = (s_t, a_t)$ .

Given any s, we have

$$\mathbb{E}_{a \sim \pi_{\lambda}^{*}(s)} \Big[ Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\lambda}^{*}(a|s) \Big] \leq \max_{\pi} \sum_{a} \pi(a|s) Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \pi(a|s) \log \pi(a|s)$$

$$= \sum_{a} \bar{\pi}_{\theta}(a|s,t) Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \bar{\pi}_{\theta}(a|s,t) \log \bar{\pi}_{\theta}(a|s,t)$$

$$= \lambda \log \sum_{s} \exp(Q_{t,\lambda}^{\pi_{\theta}}(s,a)/\lambda) \tag{A.41}$$

where  $\bar{\pi}_{\theta}(a|s,t) = \exp{(Q^{\pi_{\theta}}_{t,\lambda}(s,a)/\lambda)}/\sum_{a} \exp{(Q^{\pi_{\theta}}_{t,\lambda}(s,a)/\lambda)}$ . Notice that

$$\begin{split} V_{t,\lambda}^{\pi_{\theta}}(s) &= \sum_{a} \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\theta}(a|s) \right) \\ &= \sum_{a} \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\theta}(a|s) + \lambda \log \bar{\pi}_{\theta}(a|s,t) - \lambda \log \bar{\pi}_{\theta}(a|s,t) \right) \\ &= \lambda \log \sum_{a} \exp(Q_{t,\lambda}^{\pi_{\theta}}(s,a)/\lambda) - \lambda D_{\mathrm{KL}}(\pi_{\theta}(s,t)||\bar{\pi}_{\theta}(s,t)) \end{split} \tag{A.42}$$

Substituting equation A.41 and equation A.42 into equation A.40 yields

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_{0}) - V_{t,\lambda}^{\pi_{\theta}}(s_{0})$$

$$\leq \sum_{t=0}^{H-1} \mathbb{E}_{s \sim \mathbb{P}_{t}^{\pi_{\lambda}^{*}}(\cdot|s_{0})} \left[ D_{\mathrm{KL}}(\pi_{\theta}(s,t)||\bar{\pi}_{\theta}(s,t)) \right]$$

$$\leq \frac{\lambda}{2} \sum_{t=0}^{H-1} \mathbb{E}_{s \sim \mathbb{P}_{t}^{\pi_{\lambda}^{*}}(\cdot|s_{0})} \left\| \frac{Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot)}{\lambda} - \theta_{s,\cdot} - \frac{\sum_{a} Q_{t,\lambda}^{\pi_{\theta}}(s,a)/\lambda - \theta_{s,a}}{|\mathcal{A}|} \mathbf{1} \right\|_{\infty}^{2}$$
(A.43)

where  $1 \in \mathbb{R}^{|\mathcal{A}|}$  is an all-one vector and the last inequality follows from (Mei et al., 2020, Lemma 27).

Following the derivation of Lemma 3, it is straightforward to verify that equation A.15 holds with  $Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\theta}(a|s)$  in place of the advantage  $A_{t,\lambda}^{\pi_{\theta}}$ :

$$\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D}) = \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \pi_{\theta}(a|s) \nabla \log \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\theta}(a|s) \right)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \nabla \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \log \pi_{\theta}(a|s) \right)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \nabla \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \theta_{s,a} + \lambda \sum_{a} \exp \theta_{s,a} \right)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \nabla \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \theta_{s,a} + \lambda \sum_{a} \exp \theta_{s,a} \right)$$

$$= \sum_{t=0}^{H-1} \sum_{s} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \nabla \pi_{\theta}(a|s) \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \theta_{s,a} + \lambda \sum_{a} \exp \theta_{s,a} \right)$$
(A.44)

where third equality follows from the  $\pi_{\theta}(a|s)$  is a softmax function, and the last equality is due to the fact that

$$\sum_{a} \nabla \pi_{\theta}(a|s) \sum_{a} \exp \theta_{s,a} = \sum_{a} \exp \theta_{s,a} \nabla \sum_{a} \pi_{\theta}(a|s) = \sum_{a} \exp \theta_{s,a} \nabla 1 = 0.$$

Then from equation A.44, we have

$$\frac{\partial V_{\lambda}^{\pi_{\theta}}(\mathcal{D})}{\partial \theta_{s,\cdot}} = \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s) \sum_{a} \frac{\partial \pi_{\theta}(a|s)}{\partial \theta_{s,\cdot}} \left( Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \theta_{s,a} \right) 
= \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s) \frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} \left( Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) - \lambda \theta_{s,\cdot} \right).$$
(A.45)

where the first equality is due to the fact that  $\partial \pi_{\theta}(a|s')/\partial \theta_{s,\cdot}=0$  for any  $s'\neq s$ , and the last equality follows from a matrix-vector product rewriting.

Define  $S(s_0) \subseteq S$  as the set of sequences starting from query  $s_0$ , i.e.,  $S(s_0) = \{s_0, a_0, \dots, a_{H-1} | a_t \in A \text{ for } t \in [0, H-1]\}$ . Then we have

$$\|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\| \ge \left(\sum_{s \in \mathcal{S}(s_{0})} \left\| \frac{\partial V_{\lambda}^{\pi_{\theta}}(\mathcal{D})}{\partial \theta_{s,\cdot}} \right\|^{2} \right)^{0.5}$$

$$\ge \frac{1}{\sqrt{|\mathcal{S}(s_{0})|}} \sum_{s \in \mathcal{S}(s_{0})} \left\| \frac{\partial V_{\lambda}^{\pi_{\theta}}(\mathcal{D})}{\partial \theta_{s,\cdot}} \right\|$$

$$= C_{d} \sum_{s \in \mathcal{S}(s_{0})} \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s) \left\| \frac{\partial \pi_{\theta}(\cdot|s)}{\partial \theta_{s,\cdot}} \left( Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) - \lambda \theta_{s,\cdot} \right) \right\|$$
(A.46)

where the second and the third inequalities follow from Cauchy-Schwartz inequality. and the last inequality follows from equation A.45. The constant  $C_d = \frac{1}{\sqrt{|S(s_0)|}} = (|\mathcal{A}|^H)^{-0.5}$ .

Continuing from equation A.46, it follows similar to the derivations in (533)–(536) in (Mei et al., 2020) that

$$\|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\|$$

$$\geq C_{d} \sum_{s \in \mathcal{S}(s_{0})} \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s) \min_{a} \pi_{\theta}(a|s) \|Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) - \lambda \theta_{s,\cdot} - \frac{\sum_{a} Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \theta_{s,a}}{|\mathcal{A}|} \|_{\infty} \quad (A.47)$$

Then we have

$$\begin{split} & \|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\|^{2} \\ & \geq C_{d}^{2} \sum_{s \in S(s_{0})} \sum_{t=0}^{H-1} (\mathbb{P}_{t}^{\pi_{\theta}}(s))^{2} (\min_{a} \pi_{\theta}(a|s))^{2} \left\| Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) - \lambda \theta_{s,\cdot} - \frac{\sum_{a} Q_{t,\lambda}^{\pi_{\theta}}(s,a) - \lambda \theta_{s,a}}{|\mathcal{A}|} \right\|_{\infty}^{2} \\ & = C_{d}^{2} \lambda^{2} \sum_{s \in S(s_{0})} \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\theta}}(s) (\min_{a} \pi_{\theta}(a|s))^{2} \frac{\mathbb{P}_{t}^{\pi_{\theta}}(s)}{\mathbb{P}_{t}^{\pi_{\lambda}^{*}}(s|s_{0})} \mathbb{P}_{t}^{\pi_{\lambda}^{*}}(s|s_{0}) \left\| Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) / \lambda - \theta_{s,\cdot} - \frac{\sum_{a} Q_{t,\lambda}^{\pi_{\theta}}(s,a) / \lambda - \theta_{s,a}}{|\mathcal{A}|} \right\|_{\infty}^{2} \\ & \geq \lambda^{2} C_{\lambda}^{\pi_{\theta}}(s_{0}) \sum_{s \in S(s_{0})} \sum_{t=0}^{H-1} \mathbb{P}_{t}^{\pi_{\lambda}^{*}}(s|s_{0}) \left\| Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) / \lambda - \theta_{s,\cdot} - \frac{\sum_{a} Q_{t,\lambda}^{\pi_{\theta}}(s,a) / \lambda - \theta_{s,a}}{|\mathcal{A}|} \right\|_{\infty}^{2} \\ & = \lambda^{2} C_{\lambda}^{\pi_{\theta}}(s_{0}) \sum_{t=0}^{H-1} \mathbb{E}_{s \sim \mathbb{P}_{t}^{\pi_{\lambda}^{*}}(\cdot|s_{0})} \left\| Q_{t,\lambda}^{\pi_{\theta}}(s,\cdot) / \lambda - \theta_{s,\cdot} - \frac{\sum_{a} Q_{t,\lambda}^{\pi_{\theta}}(s,a) / \lambda - \theta_{s,a}}{|\mathcal{A}|} \right\|_{\infty}^{2} \end{aligned} \tag{A.48}$$

where

$$C_{\lambda}^{\pi_{\theta}}(s_0) = C_d^2 \min_{t,s \in \mathcal{S}(s_0)} \mathbb{P}_t^{\pi_{\theta}}(s) (\min_{s,a} \pi_{\theta}(a|s))^2 \min_{t,s \in \mathcal{S}(s_0)} \frac{\mathbb{P}_t^{\pi_{\theta}}(s)}{\mathbb{P}_t^{\pi_{\lambda}^*}(s|s_0)}.$$

Combining equation A.48 and equation A.42 gives

$$V_{\lambda}^{\pi_{\lambda}^{*}}(s_0) - V_{\lambda}^{\pi_{\theta}}(s_0) \le \frac{1}{2\lambda} \frac{|\mathcal{D}|^2}{C_{\lambda}^{\pi_{\theta}}(s_0)} \|\nabla V_{\lambda}^{\pi_{\theta}}(\mathcal{D})\|^2 \tag{A.49}$$

which completes the proof.
